

Make the most of Subversion 1.5

July 9th, 2008

SUBVERSION © 2008 CollabNet, Inc. COLLABNET

Architecture Overview

The diagram illustrates the Subversion architecture. At the top, 'Command-line client app' and 'GUI client apps' connect to a 'Client library'. The 'Client library' is linked to a 'Working Copy Management Library' and 'Repository Access' (which includes 'DAV', 'SVN', and 'local'). 'Repository Access' connects to 'Ye Old Internet (Any TCP/IP Network)'. Below the network, there are 'Apache mod_dav_svn' and 'svnserve' servers. These connect to a 'Subversion Repository', which is backed by 'Berkeley DB' and 'FSFS'. Two interfaces are highlighted: 'Client Interface' between the client apps and the client library, and 'Repository Interface' between the servers and the repository.

Flexibility at three levels of the architecture:

- Multiple clients
 - Unix, Windows, Mac
 - Command-line vs. GUI
- Multiple ways to access the repository
- Multiple data stores available

SUBVERSION COLLABNET

Subversion 1.5 - new features and their usage

- ▶ Merge tracking
- ▶ Sparse checkout
- ▶ Write/through proxy setup
- ▶ Change lists

www.collab.net COLLABNET

Merging Pre-1.5

#SME UK BCS

- ▶ Merge is utility basically outside of Subversion core
- ▶ Responsibility to decide what needs to be merged is on the shoulder of the developer
- ▶ Quality issues can arise if the developer is not diligent

SUBVERSION ————— COLLABNET

Why Merge Tracking?

#SME UK BCS

- ▶ Improves the usability
 - No more manual recordings of merges
 - Prevent unnecessary duplicate merges
 - `svnmerge.py` helps, but any merge outside of the script breaks the info
- ▶ Traceability
 - Recording what changes made it to a branch
 - The layout of the recording is now unified
 - Gives the capability to securely identify the way of a change throughout the repository

SUBVERSION ————— COLLABNET

What is Merge Tracking in 1.5?

#SME UK BCS

- ▶ Merge becomes part of Subversion vs. a utility
- ▶ It supports
 - Cherry picking of changesets
 - Documenting the manual merge of changesets
 - Preventing duplicate merges when repeatedly merging branches
 - Record manual merges outside of Subversion
 - Merge history - `svn:mergeinfo` answers merge related questions
- ▶ Supports activities when merging changes implemented by others

SUBVERSION ————— COLLABNET

Pre-1.5 - Unstable Trunk model

- ▶ What's on a branch?
 - Trunk - ongoing development for next release
 - Release branches - formal promotion process
 - Isolated development branches - experimental work
- ▶ Use cases
 - Waterfall, serial development (OpenSource)
 - Single customer with smaller team

Useful for Stable Trunk Model

- ▶ What's on a branch?
 - Trunk - stable releases
 - Release - reflects work done for a release
 - Task - isolating longer tasks with instability
- ▶ Use Cases
 - Waterfall model and overlapping development cycles
 - Larger teams

Better Support for Agile Release

- ▶ What's on a branch?
 - Trunk - stable points of releases and bugfixes
 - Release branch - release development process
 - Task branch - definable units of work
- ▶ Use cases
 - Agile development and release

#ASMF UK BCS

Why does it matter?

- ▶ The introduction of merge tracking reduces the gap between Subversion and „High-end“ version control systems
- ▶ It enables the use of Subversion in more projects
 - Long maintenance cycles
 - Many different flavours of software (customer specific changes on a common core)
- ▶ This feature allows Philips Healthcare to rely on Subversion for the core platform project
 - Enables FDA compliance with a reasonable effort

#ASMF UK BCS

Simplified Audit Trail

- ▶ Tracks changes that are propagated through various branches
- ▶ If Subversion is deployed with an integrated tracker, issues are linked to revisions (changesets)
- ▶ Disclaimer: limitations of the 1.5 implementation
 - If the file structure differs heavily between 2 branches, potential conflicts might not be treated in the expected way
 - Example: a file has been moved in a branch, but modified in another branch
 - Visit the Subversion project to review tree conflict work going on

#ASMF UK BCS

Sparse Checkouts

- ▶ The problem: unnecessary data in your working copy
 - Modules you never edit
 - Large files that are kept along with source code (for example, build results, documents)
 - Sibling projects in the same repository
- ▶ Sparse checkouts give you the capability to opt-in/opt-out parts of the repository tree
 - Based on a directory tree depth selection
 - Selected depth is „sticky“ and maintained on the following operations

#SMF UK   BCS

Sparse Checkouts

- ▶ Adds a new `-depth` option
 - .. to `svn checkout`: selects the initial working copy depth
 - .. to `svn update`: modify a previous selection
 - .. to most of the other subcommands
 - Universally supercedes the `-recurse` and `-non-recurse` options
 - Limits the scope of operations
- ▶ Does not require a Subversion 1.5 server!
 - When requesting depths from older servers, the client does the filtering to remove out-of-scope data
 - A server upgrade is still recommended to improve the performance

#SMF UK   BCS

Improve the Workspace Management

- ▶ Minimizes the update, creation and switch time of workspaces
 - Speeds up day-to-day operations
- ▶ Minimizing the resource utilization on the clients
- ▶ Taking away the time pressure to optimize „grown“ repositories
 - Pre-1.5 you had to re-org your repository if the structure was not well planned

#SMF UK   BCS

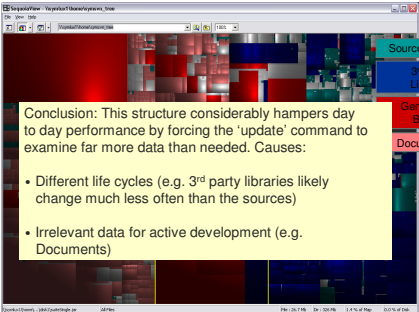

Good time to review the repository structure

- ▶ Distinguish groups to examine update frequency during common activities (e.g. regular development, testing, maintenance)
 - e.g. source code, 3rd party libraries etc.
- ▶ Use a tool like SequoiaView to create a graphic overview
 - Exclude the `.svn` directories when you run it on a working copy
 - Tailored color coding helps to identify the categorie you are interested in

Analysis - Real-life Example

USMf UK
BCS

Conclusion: This structure considerably hampers day to day performance by forcing the 'update' command to examine far more data than needed. Causes:

- Different life cycles (e.g. 3rd party libraries likely change much less often than the sources)
- Irrelevant data for active development (e.g. Documents)

SUBVERSION
COLLABNET

WebDAV Write-through proxies

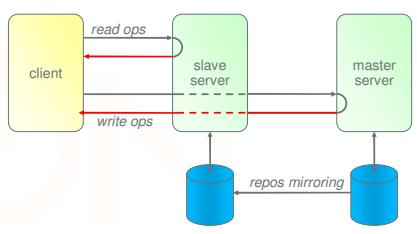

USMf UK
BCS

- ▶ Allows Subversion servers to pass data changing activities to another server
- ▶ Enables singlemaster/many slave server repository setups
 - Clients interact 90% of the time with a local slave server to cover the read activities
 - All write activities (commit, property changes, lock/unlock) are passed through to the master repository
 - The master propagates any changes back to the slave servers
 - Replication and re-sync is done with svnsync (introduced in 1.4)

SUBVERSION
COLLABNET

WebDAV Write-thru Proxies

USMf UK

SUBVERSION
COLLABNET

USMF UK BCS

Some Use Cases

- ▶ **Using mirrors gives you an online mirror to improve high-availability**
 - In case of a server failure user can still work read-only immediately
 - Extends the time slot to correct the server problem
- ▶ **Using mirrors helps with a backup strategy**
 - The online mirror can be kept up-to-date immediately (via hook script)
 - The dump of a mirror can be used to recreate the master

SUBVERSION ————— COLLABNET.

USMF UK BCS

Work Distributed

- ▶ It is a different approach as the traditional replication model
- ▶ Subversion has been optimized to live in the internet
- ▶ Based on the experiences the performance is often a perceived problem
 - Consider when dealing with large files and limited bandwidth
 - Try the central approach first
 - Balance performance increase vs. infrastructure overhead

SUBVERSION ————— COLLABNET.

USMF UK BCS

Change list

- ▶ Changelists are a new client only feature
- ▶ Groups files to limit the scope of operations (e.g., log)
- ▶ Use a seeding concept for working copies to share changelists
 - A working copy with a baseline is created on a server
 - Authentication information is stored outside of the working copy
 - Simple copy and re-use
- ▶ Example: Subversion user from the financial sector improved compliance by eliminating errors during commit

SUBVERSION ————— COLLABNET.

Summary #SME UK BCS

- ▶ Subversion 1.5 provides a lot of new capabilities that improve day-to-day activities
- ▶ Evaluate before rolling out
 - Define clear rules (i.e. naming conventions)
- ▶ Ensure that developers get trained
